

Non-reversible beats reversible anchored Langevin — ill-conditioned design, $s = 5.0$

$d = 9$; constraint: unit ball; AR(1) predictors $\rho_x = 0.99$ (posterior condition number 1225); $h = 0.0001$; $m = 50$; $R = 100$; iterations = 1000; anchor $\rho = \log 2$ for BOTH methods; block strengths $s = (5.0, 5.0, 5.0)$.

Accuracy axes are windowed on the plateau (a 0.002 difference is invisible at full scale); bands are mean ± 1 sd across replicates (repeat-run variability, NOT confidence or credible intervals). The right panel carries the evidence: the paired difference with ± 2 SE. Held-out-seed confirmation: mean diff +0.0024 over 3 independent seed batches.
