

Non-reversible vs reversible anchored Langevin

$d = 9$; constraint: unit ball; AR(1) predictors $\rho_x = 0.99$ (posterior condition number 1225); step size $h = 0.0001$; mini-batch $m = 50$; repeats $R = 100$; iterations = 1000; anchor $\rho = \log 2$ for BOTH methods; block strengths $s = (5.0, 5.0, 5.0)$. Lines are the across-replicate mean; bands are mean ± 1 sample sd (ddof = 1) of single-iterate accuracy, i.e. repeat-run variability -- NOT confidence or posterior credible intervals. The vertical axis is windowed on the plateau, not $[0, 1]$.
